standards Category:Autodesk Category:Unified modeling languagesThis invention relates to a new control device, method of manufacture, and method of use, for the control of reciprocating-type machines, and in particular, for the control of an electric motor that drives a device such as a pump, compressor, or a brake. Devices of this type are often used for the purpose of driving equipment that is moved back and forth. For example, elevators are often driven by linear motors, and materials handling machines such as cranes are often driven by electromotors. There are various advantages to the use of electromotors over other types of motors. The advantages include lower cost, lower weight, and more compact size. Also, the output torque of an electromotor is inherently controllable. Moreover, the electric motor in an electromotor is in a floating position, which allows the actuator to be used as an actuator, a motor, or a servo unit. One area in which it is especially useful to have an actuator that is switchable between multiple modes of operation is in the use of a linear motor, such as in an elevator, to drive a piston back and forth. For example, in an elevator a motor that moves a piston back and forth to lift or lower an elevator car is often used to raise or lower the elevator car and thus to move an elevator passenger from floor to floor. In such a case it is often desirable for the motor to be switchable between a position to drive the piston forwardly for a short distance so as to raise the elevator car, and a position to drive the piston back for a longer distance to lower the elevator car. For convenience of use, it is often desirable to provide this mode of operation in a control device that is simple to operate and requires only small amounts of space, since a small control device will be located near the motor. There are various control devices known for use in controlling the operation of a linear motor. For example, U.S. Pat. No. 5b5f913d15
